

DustWatch Report

July 2023

Dust activity	Very little dust activity across the network
Wind strength	Very low wind, less than long-term average
Groundcover	Unchanged from June 2023, reached winter peak
Rainfall	Below average in the east, above in the north west

Dust activity

Almost no dust activity was recorded in July 2023, apart from some minor activity in the local Land Services Central West Region (Figure 2). A major reason for the low dust emissions is the unusually low wind strength, as expressed in hours of wind > 40 km/h (Figure 1).

Wetter than average conditions in the west (Figure 7a) are the other factor contributing to the low dust emissions.

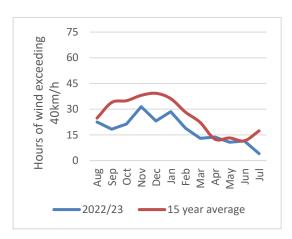

Figure 1 Hours of wind exceeding 40 km/h – average across all sites

Note: Real-time dust measurements from all our monitoring sites are at: Rural air quality network - live data

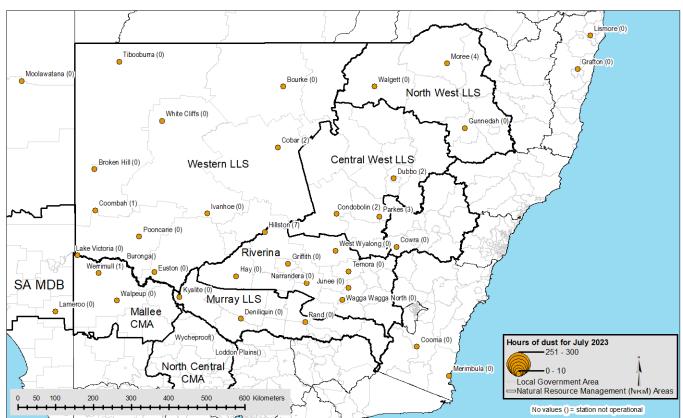

Figure 2 Hours of dust activity (number in brackets) at each DustWatch site in July 2023

Groundcover

The area with greater than 50% groundcover (green and yellow colours in Figure 3) has remained almost unchanged from June 2023 (Table1). The Local Land Services Western Region remains the area with the lowest groundcover. Saying that, 90% of the area remains above 50% cover and is therefore protected from wind erosion.

May 2023	99	97	100	100	98	100	97	86	100
Jun 2023	100	99	100	100	99	100	98	90	100
Jul 2023	100	100	100	100	98	100	98	90	100

Groundcover change

Groundcover reached its winter peak in June 2023 and started declining in July 2023 in the Local Land Services North West region (Figure 5). If the below-average rainfall predicted by the Bureau of Meteorology for spring/summer 2023 eventuates (www.bom.gov.au/climate/ahead/outlooks), the area with groundcover above 50% could drop as low as 45% for the Local Land Services Western Region, similar values to 2017 (brown line in Figure 5).

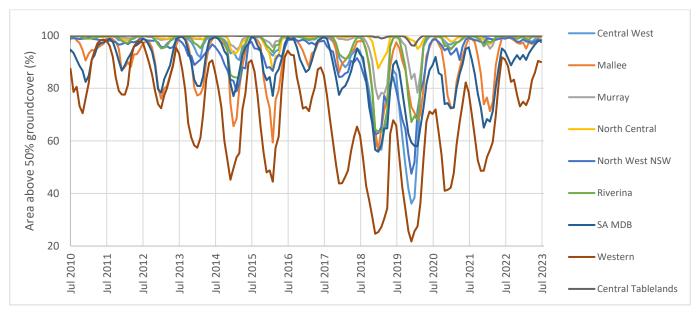

Figure 5 Area (%) of NRM with more than 50% cover since July 2010

Rainfall

Total rainfall in July 2023 was average to below average for most of New South Wales (Figure 7a). The only exception is the far west of the state, where welcome rain between 10 mm and 25 mm was recorded in the gauges (Figure 6). In contrast, the eastern half of the state is unusually dry, with close to no rainfall recorded in the south east.

The unusual picture of wetter than average in the west and dryer than average in the east continues and is reflected in the 3 monthly deciles map (Figure 7b).

VIIRS fires and satellite image

Haze from smoke and dust is difficult to separate. We use satellite imagery to manually classify every measurement into dust or smoke. The satellite detected 1830 hot spots (375m pixel with temperature anomalies) in July 2023 (Figures 8 and 9), very similar to the 1935 hot spots detected in June 2023. A mix of hazard reduction and stubble burning is the predominant cause of the fires.

Note: The number of hot spots is not equal to the number of fires. Large fires have multiple hot spots, thereby increasing the number of detections. Cloud or fog can obscure hot spots, thereby reducing the number of detections.
