

Native Plant Species Recorded in Western Sydney

A complete listing of native plant taxa recorded for western Sydney including distributional records for 12 local government areas, compiled from existing plant species lists, UBBS field surveys, herbarium records and the listing prepared by Benson & McDougall (1991). Over 250 plant species lists have been used in the compilation, however, it is not an exhaustive coverage.

For each plant taxon the list provides a record of the number of sites recorded for each of the twelve local government areas. The number of NPWS conservation reserves in which each species is represented is also provided (see key for explanation of coding). Based on this information the conservation status of each species is assessed. Taxa occurring in 3 or more reserves are considered to be **conserved (C)** and those in less than 3 reserves are identified as **vulnerable (V)** in western Sydney. Due to the limited distribution of sandstone habitats within the study area and the existence of several conservation reserves in surrounding plateaus, however, sandstone species are considered to be adequately conserved within western Sydney if present in two or more reserves. References are provided for the records on an LGA basis.

Key to NPWS Conservation Reserves:

- A- Agnes Banks Nature Reserve
- B- Bents Basin but now Gulguer Nature Reserve
- Bm- Blue Mountains National Park
- Ca- Cattai National Park
- Cs- Castlereagh Nature Reserve
- G- Georges River National Park
- M- Mulgoa Nature Reserve
- Mi- Mitchell Park (part of Cattai N.P.)
- Pi- Pitt Town Lagoon N.R.
- S- Scheyville National Park
- W- Windsor Downs Nature Reserve
- Wf- Wisemans Ferry Historic Site -*not strictly a conservation reserve

Limitations

Not all available plant lists or information sources could be used for the compilation of these lists within the time constraints of the project, however, priority was given to those considered to be the most comprehensive and reliable. The lists provide a “snap shot” of the present state of our knowledge concerning the distribution and conservation significance of native plant species in western Sydney, and provides a sound basis for regional and local biodiversity conservation management. It is important, however, that new records and information continue to be fed into the system and the lists updated accordingly to progressively improve our knowledge base. As more records are incorporated it is expected that the number of regionally significant (REG) taxa (those qualifying due to rarity criteria) will decline. Considering the size of western Sydney and

the current levels of development, however, there is a strong argument for raising the level of rarity from 5 to 10.

There is inevitably a bias towards greater representation of trees and shrubs in most species lists available as they are both more visible and easier to identify. In contrast grasses, sedges, rushes, orchids and smaller herbs are more cryptic and identification considerably more difficult. Such a bias will result in a poorer understanding of the distribution and conservation significance of these taxa. A large proportion of the sedges and rushes, for example, are rated as being regionally significant (REG) and rare in the region. Although this will partly reflect the scarcity of wetland and riparian habitats, it also indicates a lack of identification skills in the field. To help compensate for this bias in the present study a greater effort was made to check and incorporate herbarium records for these particular groups.
