State Plan target

By 2015 there is an increase in the number of sustainable populations of a range of native fauna species.

Background

New South Wales has experienced severe declines and extinctions of a broad suite of native fauna since European settlement, with 26 species of mammals, 12 species or subspecies of birds, one species of reptile, one marine fish and one invertebrate listed as presumed extinct under threatened species legislation. The introduction of exotic predators (cats, foxes and rats) and herbivores (rabbits, goats and sheep), clearing and disturbance of native vegetation, changes to fire regimes, changes to water flows, the introduction of exotic diseases, overfishing and fishing by-catch are likely to have been the major causes of fauna declines.

Within the Hawkesbury–Nepean region, five of the 606 species of terrestrial vertebrates recorded since European settlement have become extinct. A further 11 species (14 per cent) of mammals, 42 species (11 per cent) of birds, 10 species (20 per cent) of amphibians and 16 species (17 per cent) of reptiles are estimated to have lost at least half of their pre-European distribution (Figure 1).
Map of the catchment

Assessment

Condition

Indicators: sustainability of terrestrial vertebrate species

The sustainability (condition) of individual terrestrial vertebrate species within the region was assessed using modified IUCN Red-List Criteria (IUCN 2001). In particular, estimates of total population size and distribution, trends in population size and distribution over time, and direct estimates of extinction risk from population modelling were used to score sustainability for each species at the regional scale. Species were assessed only if they were being actively monitored at a regional or larger scale. Species were scored as data deficient if the uncertainty in the assessment was large. As a result, relatively few species have been assessed, but confidence in most of the assessments is medium to high. Given that this is the first such assessment of the sustainability of terrestrial vertebrates at the regional scale, data on trends in sustainability is not available.
In the Hawkesbury–Nepean region, 51 species (13 per cent) of birds, no mammals, no amphibians and no reptiles were monitored adequately to assess sustainability (Figure 2). The relatively large number of assessments for birds reflects the large number of surveys conducted across much of NSW as part of Birds Australia's Atlas of Australian Birds project. Of all assessable species within the Hawkesbury–Nepean region, five (10 per cent) scored good or very good for sustainability. By comparison, 76 species (35 per cent of assessable species) across NSW scored good or very good for sustainability.

Index of fauna sustainability

An index of fauna sustainability was calculated as the mean of sustainability scores for all individual species that were able to be assessed. Although scores for individual species are categorical rather than continuous, the mean will reflect net changes in the sustainability of individual species over time. The index is biased towards the groups of species for which there is the most data (birds). It is the objective of the fauna program of the NSW Natural Resources monitoring, evaluation and reporting strategy to increase the number of assessable species.

Pressures

The major causes of historical declines in native fauna remain the major pressures on sustainability. These are:

- the introduction of exotic predators (see also the invasive species report)
- the introduction of exotic herbivores and overgrazing by exotic and native herbivores (see also the invasive species report)
- the clearing and disturbance of native vegetation (see also the native vegetation report)
- changes to fire regimes
changes to water flows (see also the riverine ecosystems, groundwater dependent ecosystems, and wetlands report)
the introduction of exotic diseases
overfishing and fishing by-catch (see also the marine waters and ecosystems report).

The interaction between these pressures and their impacts on native fauna is complex and cannot be easily summarised. For example, cats and foxes have been linked to more extinctions of fauna in NSW than any other factor and they remain a threat to most ground-dwelling species across the state. Nevertheless, the impacts of cats and foxes vary greatly between species and at different times, and are influenced by environmental factors. Moreover, impacts are not closely related to density; low numbers of cats and foxes can have devastating impacts on highly-vulnerable species at certain times. Thus changes in the threat posed by cats and foxes cannot be readily mapped or monitored through time at a regional scale. This difficulty applies to deriving indicators for most of the other major pressures on fauna. In the absence of such indicators, case studies of impacts and/or management responses can provide useful insight.

Management activity

State level

The native fauna target is being addressed at the state level through the protection of critical habitat, control or eradication of priority pest animals, regulation of native vegetation clearing and urban development, and undertaking research on fire regimes. Some threats, most notably those posed by cats and chytrid fungus, remain largely unaddressed due to the lack of effective control techniques.

Some specific activities include:
control of pest animals, through:
- targeted cross-tenure control of foxes in priority areas through the NSW Fox Threat Abatement Plan (NB state-wide control is not achievable with current methods)
- broad-scale rabbit control through the release of myxomatosis and rabbit haemorrhagic disease
- the eradication of rats, mice and rabbits from several NSW islands

habitat protection, through:
- the regulation of the clearing of native vegetation on rural lands and harvesting of timber on forestry lands, and the consideration of important habitat corridors in planning for urban development
- dedicating about 8.4 per cent of NSW as conservation reserve
- specifically managing about 2.2 per cent of private and other public lands in NSW for conservation under Wildlife Refuges and Conservation Agreements
- incentive programs to improve vegetation condition and extent through replanting and grazing management on private lands (but these are often small scale)
- environmental flow allocations for water
- identifying the most important habitats for the priority fauna species of the catchment, based on the habitats' significance for threatened species and value as high quality habitat
identifying priorities at the property scale to focus conservation efforts, including biobanking opportunities within high value fauna habitats.

- research, including:
  - researching the relationships between fire and the population dynamics of a range of Australian flora and fauna, allowing optimal fire regimes for threatened taxa to be considered in fire planning.

**Regional level**

At the regional level, the Hawkesbury–Nepean CMA is undertaking the following activities in relation to the native fauna target:

- providing incentives to landholders to protect and enhance vegetation within regional biodiversity corridors, and improve corridor function as fauna habitat
- providing incentives to landholders, both directly through CMA programs and indirectly through council-delivered programs, to protect and enhance riparian and wetland vegetation, riparian corridors and aquatic habitat
- identifying and prioritising known and potential threatened flora sites on private land in the northwest of the catchment, to assist with conservation
- supporting priority habitat corridor management and protection with councils and the Department of Planning
- supporting actions to preserve and improve populations of threatened species across the catchment, and targeting community engagement through the identification and promotion of icon species.
