State Plan target

By 2015 there is an increase in the area of land being managed within its capability.

Background

Land ‘capability’ is the inherent physical capacity of the land to sustain a range of long-term uses and management practices without degradation to soil, land, air and water resources (Dent & Young 1981). It is a function of various landscape features and processes, including terrain, soil and climatic attributes, as well as their interactions. Failure to manage land in accordance with its capability may result in degradation of resources both on and off site, leading to a decline in natural ecosystem values, agricultural productivity and infrastructure functionality. The management of land within its inherent physical capability is vital for the sustainable use of soil and land resources.

Land management deals with human practices followed during the course of land-use. Management actions, such as the intensity of tillage prior to sowing, length of bare fallow, maintenance of ground cover and the extent of fertiliser application, all impact on the land. Land-uses considered in this report include various forms of cropping, grazing, horticulture, forestry and nature conservation. Current land management practices associated with these land-uses are also considered against land degradation hazards. These hazards include sheet erosion, gully erosion, wind erosion, soil structure decline, organic carbon decline, soil salinity, soil acidification and acid sulfate soils.

A detailed technical report describes the methods used to derive the information contained in this report. At the time of publication of the State of the catchments 2010 reports, the technical reports were being prepared for public release. When complete, they will be available on the DECCW website: www.environment.nsw.gov.au/publications/reporting.htm.

Note: All data on natural resource condition, pressures and management activity included in this SOC report, as well as the technical report, was collected up to January 2009.
This report outlines the level of sustainable land management across the Sydney Metropolitan region. It provides information for setting and adjusting natural resource management (NRM) targets and associated resource allocation. Land management within capability closely relates to soil condition, which is also discussed in this report.

**Map of the catchment**

The 10 soil monitoring units (SMUs) that were the focus of assessment within the Sydney Metropolitan region are shown in Figure 1. An SMU is a large tract of land where changes in soil condition and land management can be periodically observed. SMUs usually have a relatively homogeneous pattern of soils, parent material, geomorphology and climate. The SMUs were selected by DECCW and Sydney Metropolitan Catchment Management Authority (CMA) staff on the basis of their area, importance, pressures and vulnerability. They collectively covered 780 km² or 38 per cent of the region.
Assessment

The project was designed to assess changes in land management, relative to land capability, over time on the most important soils in New South Wales. It involved a comparison of the potential impact of land management actions against soil and land conditions of the sites to derive ‘land management within capability’ indices. The resulting process is summarised in Figure 2 and briefly described below. It is further detailed in Gray et al. (2008) and the supporting technical report.
Step 1 – the assessment commenced with the collection of soil and land data at each of the permanent soil monitoring sites established within each SMU. This is further described in the protocol document (DECCW 2009).

Step 2 – a questionnaire was used to collect land management data. This was completed by the landholder and detailed precise management actions for each site (DECC 2008). As of March 2009, 20 monitoring sites had been established in the Sydney Metropolitan region, all of which have had land management surveys returned.

Step 3 – land and soil ‘capability’ (LSC) of each site was determined using a rule-set, together with the recorded land and soil attributes (Murphy et al. 2008). Ratings ranged from one (most capable) to eight (least capable) for each land degradation hazard.

Step 4 – the potential impact from the combined land management actions was determined, corresponding to an upper allowable LSC for each hazard. This was based on a rule-set prepared with the aid of literature values and expert knowledge and approved by DECCW, CMAs and Industry & Investment NSW (I&I) staff.
Step 5 – the potential impact of the land management actions was evaluated against the actual conditions of the site by comparing the above two derived values (LSC and upper allowable LSC) (see Table 1). Where the potential impact of actions exceeded what could be sustained by the land, the land was rated as being managed beyond its capability.

Step 6 – results were then converted to the ‘land management within capability’ index, using the rules given in Table 1. The index indicates the degree to which the land is managed in accordance with its natural ability to sustain long-term uses. An index of five indicates very good, highly sustainable land management where the risk of land degradation is very low. An index of one indicates very poor, unsustainable land management, with a very high risk of land degradation.

Step 7 – indices for each hazard at each site were combined for the whole site and combined again to find an average for each SMU. Where significant differences were apparent, expert knowledge gained from DECCW and CMA staff familiar with local land management practices was used to validate the results and modifications made.

Step 8 – the indices were further combined to give an overall index rating of sustainability for the entire Sydney Metropolitan region.

**Table 1  Comparison of upper allowable LSC with actual LSC**

</tbody>
</table>

**b** Range of indices: pie chart shows variation in LMwC indices for the different hazards in each SMU

**c** Worst indicators and index: gives the indicators (or hazards) of most concern in the SMU, with the associated LMwC index

**d** Data source:

- **B** Baseline data for soil condition – from field and laboratory measurements
- **L** Landholder survey on land management
- **K** Expert knowledge – from DECCW and CMA staff

**e** Data confidence:

- **High** Derived from numerous landholder surveys and field data from representative sites in the baseline study, and validated using expert knowledge
- **Medium** Derived from limited landholder surveys and field data from sites in the baseline study or roadside surveys, in conjunction with expert knowledge
- **Low** Derived from modelling or expert knowledge only

**Overall index:**

- **Catchment**: 2.7
- **State**: 3.0

---

**Legend for Table 3**

- **a** Land Management within Capability (LMwC) Index: see Table 2
- **b** Range of indices: pie chart shows variation in LMwC indices for the different SMUs for each hazard (indicator)
- **c** Apparent trend in land management relative to capability as gained from the formal expert knowledge surveys:
  - "Improving": there appears to be a steady adoption by landholders of more sustainable land management practices, leading to an improvement in soil and land condition.
  - "Steady": no change: there is no apparent move towards or away from more sustainable practices.
  - "Declining": there appears to be a general move away from sustainable practices, leading to a decline in soil and land condition.
d SMUs of concern: gives the SMU numbers for which the LMwC index is poor (<=2.5)
e Data source and confidence: see Table 2

Figure 3  Sydney Metropolitan region with average index classes for land management within capability for the SMUs

Pressures

The broad pressures that control the extent of land management within capability in the Sydney Metropolitan region are complex and beyond the scope of this project to assess and monitor. They are partly dealt with in the socio-economic monitoring themes and include issues such as:

- financial, technical and managerial capacities of landholders
- knowledge and perceptions of sustainable land management practices by landholders
- market dynamics of agricultural products and production costs
- tax and government financial and legislative settings to promote sustainable land management
- long-term climatic changes, such as increasing severity of droughts.

Management activity

The management activity for the soil condition theme and the land management within capability theme are very similar, as both centre on promoting the adoption of sustainable land management practices by landholders.

Increasing the area of land being managed within capability is one of NSW’s NRM targets as outlined in the NSW State Plan.

Addressing the target within the Sydney Metropolitan region involves initiatives and programs at the state and regional levels that will ultimately bring about the adoption of best land capability-sensitive management practices by landholders.
State level

The NSW Government guides NRM through various legislation, policies, strategies and programs.

**Legislation**

The *Catchment Management Authorities Act 2003* established the 13 CMAs and continues to outline their broad responsibility for NRM in their regions. The *Soil Conservation Act 1938* provides for the conservation of soil resources; however, its role in effective soil management has diminished over time. Various other Acts provide direct and indirect mechanisms for soil protection and management, including the *Protection of the Environment Operations Act 1997*, *Environmental Planning and Assessment Act 1979*, *Native Vegetation Act 2003* and the *Crown Lands Act 1989*.

**Policies and strategies**

The State Soils Policy (1987) sets out important principles for the protection and management of NSW soils. It has recently been reviewed and is undergoing public consultation. Other significant policies and strategies include:

- Total Catchment Management Policy (1987) – aims to ensure the coordinated use and management of land, water, vegetation and other natural resources on a catchment basis
- Sustainable Agriculture Policy (1998) – aims to facilitate a change in agricultural production in NSW towards ecologically and economically sustainable practices and farming systems
- NSW State Salinity Strategy (2000) – aims to slow down the increase in salinity and lay the foundations for future salinity management
- State Environmental Planning Policy (SEPP) Rural Lands (2008) – aims to facilitate the orderly and economic use and development of rural lands for rural and related purposes.

**Programs**

A number of relevant programs operate at the state level:

- **Monitoring, evaluation and reporting (MER) program** – DECCW is responsible for continuing its MER program and completing a baseline across all CMAs relating to soil condition and land management. The Australian Department of Agriculture, Fisheries and Forestry is funding a pilot program for national monitoring of water and wind erosion, soil acidification and soil carbon. The SoilWatch soil condition performance monitoring kit is being developed to complement and supplement MER surveillance monitoring throughout the state
- **Soil and land-use mapping** – much of eastern and central NSW is covered by soil landscape mapping at 1:100,000 or 1:250,000; this is primarily undertaken by DECCW. DECCW is also carrying out salinity mapping in the Sydney Metropolitan region. A program of detailed land-use mapping across the state is nearing completion
- **Assessment systems** – a number of soil and land assessment systems have recently been developed that will ultimately lead to more sustainable land management. These include:
  - a system to assess the impact of various land management actions on soil condition
  - an LSC assessment system, with draft mapping completed across NSW
  - soil and landscape constraint assessment system
  - the Tools2 (SLICK) modelling system which allows for assessment of the impact on soils from different management options
• **Information exchange and advice** – soil and landscape information and land management advice is provided through various publications, maps and databases (see www.environment.nsw.gov.au/soils/index.htm). The NSW Soil and Land Information System (SALIS) is run by DECCW and is intended as the single soil data base for soil information in NSW. The Natural Resource Atlas (www.nratlas.nsw.gov.au) is used to access publicly available soil profile information. The NSW Land Management Database is being developed and distributed to CMAs throughout the state. Extension services that encourage sustainable land management practices by landholders are undertaken widely by I&I staff throughout the state.

• **Research** – Research programs aimed at improving soil condition, productivity and sustainable land management practices are carried by various national and state institutions, including the Commonwealth Scientific and Industrial Research Organisation, universities, I&I, DECCW and rural industry bodies (eg Grains Research Development Corporation).

### Regional level

The Sydney Metropolitan Catchment Action Plan (CAP) will be the key document that coordinates and drives the effort to improve natural resources across the region. It describes the whole-of-Government approach to soil condition and sustainable land management targets and sets the direction for investment in NRM over the next 10 years. A draft of the Sydney Metropolitan CAP has been developed and is currently being considered by the Minister.

The draft CAP includes specific targets, with specific areas (hectares), that will address the broader state targets. These will be achieved through the following:

**Data collection**

This involves the development of a baseline of soil information and the collection of land management data over individual properties.

**Planning**

Priority issues will be identified, as well as locations for improved land management and associated investment.

**Collaboration**

Partnerships will be formed with farming organisations, industry groups, relevant government agencies (particularly DECCW, I&I, the Land and Property Management Authority), tertiary institutions, Landcare and similar community groups and individuals.

**Awareness and skills-raising**

Training days and workshops have been held, such as salinity training and capacity building workshops for local government and industry.

Guidelines and information sheets have been produced, eg Bushcare’s Training and Field Guide for Bush Generators.

**Contracts and programs with landholders**

Contracts will be developed with landholders to modify and improve land management practices. Incentive programs, aimed at improving land management practices, have also been implemented.
**Continued monitoring and evaluation**

Monitoring programs to assess progress towards the targets will continue under CMA and DECCW programs.

Other programs include Erosion and Sediment Control in Bushland Area.

Further details and examples of many of these activities are reported in the CMA’s recent annual reports.

Other regional or local based bodies and programs that aid in improved land management include:

- local councils, through their compliance with the *Local Government Act 1993* and local or regional planning instruments such as local environmental plans and regional environmental plans – many councils are participating in the Local Government Salinity Initiative and a local government engagement and capacity-building program in regional NRM. Warringah Council is involved in soil and sediment control in urban bushland
- Landcare groups that facilitate improved landholder knowledge and on-ground works – Appin Bushland-users Group is involved in soil and sediment control in urban bushland
- universities that undertake research programs in the region – University of NSW and Australian National University are involved in salinity mapping in the region.
